

## THOUGHT NOTE ON MODULE ASSIGNMENT 1

- I created a Tourism Company Website for my city (Pauri) where I add links related to About us, contact us and Climate and also added many images of Pauri and write about it in it and also linked to a Wikipedia page.
- I learned how to build a website on Tourism with the help of many html tags and attributes, etc. Let me introduce all that what I learned below.
- First, I created the structure of my tourism company with the help of html structure.
- I learned about a lot of tags like
  - <title> tag which is used to give the title of the document.
  - <body> tag is used to write all the content of the web page.
  - <a> tag – called a anchor tag used to link a web page or an image to a web page.
  - <h1> tag which are used for giving the heading. Others heading tags are in decreasing order h2, h3, h4, h5, h6.
  - <em> is used for italic the style of text.
  - <u> is used to underline the text.
- I also learn about new things like.
  - &deg ; used for giving the degree to a number.
  - &nbsp; used for giving space between the lines.
- <div> is used to write the elements or content in block level and is used to select all.

- `<span>` tag is an inline element tag use to select a particular content.
- `<img>` tag is used to add the image to the web page.
- Padding technique is used to give the space between the content and the border of a table here.
- Width and height attribute is also used to give the dimension.
- Alt attribute is used inside the image tag when there is a problem in loading the image then alt attribute is used to show the text which is written, and it is also helpful for visually challenged peoples.
- I learn about comment tags `<!-->` used to give a hint to another developer or when we need to do changes in the code.
- `<table>` is used to create a table and this tag consists of sub-tags to represent the row, heading and data of a table as table row represented as `<tr>` , table header tag as `<th>` , table data tag as `<td>`.
- `<iframe>` tag is used to link another page to the existing page, and we can also change the border of frame of the another page using `frameborder` attribute and also give the title to it so that one finds it easy.
- `<br>` tag is used to break the line.
- `<p>` tag is used to write the paragraph of a web page.

- <form> tag is used to make a form for the user who are using it so that he/she can fill his details so that we can contact the user.
- <input> tag is used as a property of form tag and used to give the input by the user related to the type of data as number, email, text, etc.
- Placeholder attribute is used inside the input or textarea tag so that user knows what to write inside the form as pre-information.
- <textarea> tag is used to write a a lot of text like address, reviews, comments, etc.
- <button> tag is used to create a button for the form.
- <link> tag is used to link the external style sheet file to the html file of our web page.
- Rel attribute is used to create a relationship between html and CSS file.
- href attribute is used to link the hypertext of a website to our html page.
- I also learn about creating links as images.

These are all my learning outcomes of HTML and some CSS commands which I use in this Project.

Note: There are still a lot of commands and things which I didn't mention here because it will be never ending or lengthy and consume a lot of time to write (I prefer to code and explain )but still anyone can ask anything related to the project directly to me)

THANK YOU.
